

Coastal Engineering Technical Note

FALL VELOCITY OF BEACH SANDS

PURPOSE: To present an improved method for estimating the terminal fall velocity of any beach sand. Fall velocity is used in predicting the occurrence of accreted (berm) or eroded (bar) nearshore profiles; see Section 4.525c of the Shore Protection Manual. Although definitive methods for engineering application have not yet been established, the fall velocity is expected to figure in the dimensions of bed forms and in the sediment transport.

BACKGROUND: Standard guidance on the value of fall velocity is provided for spheres of a given material in a given fluid; for example, Figure 4-31 of the SPM presents the fall velocity of quartz spheres in freshwater at several temperatures. A recent review of available measurements resulted in a set of simple equations giving fall velocity for common angular sediment grains. This more general and convenient guidance will be summarized here, and an example calculation presented.

GIVEN GUIDANCE: To estimate fall velocity, V_f , the following material characteristics must be specified: ρ_s = sediment density; ρ = fluid density; ν = fluid kinematic viscosity; and M_d = sediment median grain diameter. To determine which of the three equations should be used, the grain buoyancy, A, must be determined using the following equation:

$$A = \frac{(p_s - p)g H_d^3}{q v^2}$$

where g = acceleration of gravity. The fall velocity equations and their ranges of applicability are:

$$V_{f} = \frac{(\rho_{-g} - \rho)g M_{d}^{2}}{18\rho v}$$
 for A < 39 (1)

$$V_{f} = \frac{\left[\frac{(\rho_{g} - \rho)g}{\rho}\right]^{0.7} H_{d}^{1.1}}{6 v^{0.4}}, \text{ for } 39 < A < 10^{4}$$
(2)

$$V_{f} = \left[\frac{(\rho_{8} - \rho) g \, H_{d}}{0.91 \, \rho}\right]^{\frac{1}{2}}$$
, for $A > 10^{4}$ (3)

Any consistent units may be used in these relationships. Common values of p and u for freshwater and for 33 parts per thousand (ppt) saltwater are listed in the table. The value of g is 981 cm/sec 2 . Common values of ρ s are 2.65 gm/cm³ for quartz and 2.7 to 2.8 gm/cm³ for shell material. Equation (2) will usually be applicable in freshwater or saltwater for fine to coarse quartz sapd, i.e., $M_{\mbox{\scriptsize d}}$ between 0.125 and 1 mm.

Table. Common Fluid Characteristics				
Temperature OC	Freshwater		33 ppt Saltwater	
	ρ, 8m/cm ³	υ, cm²/sec	ρ, gm/cm ³	υ, cm²/sec
5 10 15 20 25	1.0000 0.9997 0.9991 0.9982 0.9969	0.0151 0.0130 0.0114 0.0100 0.0089	1.028 1.027 1.026 1.025 1.024	0.0157 0.0135 0.0119 0.0105 0.0 095

GIVEN: Quartz sand of $M_d = 0.02$ cm (0.20 mm) in 20° C freshwater;

FIND: The value of fall velocity, Vf.

SOLUTION: Using values from the table, the value of A is computed as:

* * * * * * * * * * * * * * * * * EXAMPLE * * * * * * * * * * * * *

$$A = \frac{(\rho_{g} - \rho) g H_{d}^{3}}{\rho v^{2}} = \frac{(2.65 - 0.998) 981 (0.02)^{3}}{(0.998) (0.0100)^{2}} = 130 ,$$

so that Equation (2) is appropriate, and

$$v_{f} = \frac{\left[\frac{(\rho_{s} - \rho)g}{\rho}g\right]^{0.7}H_{d}^{1.1}}{6 v^{0.4}} \qquad \frac{\left[\frac{(2.65 - 0.998)981}{0.998}\right]^{0.7}(0.02)^{1.1}}{6(0.0100)^{0.4}} \qquad \frac{2.51 \text{ cm/sec or }}{0.082 \text{ ft/sec}}$$
